“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

3 **ABSTRACT:** We report a thiol-ene click strategy for the preparation of a novel phenylboronic  
4 acid-functionalized covalent organic framework (COF) for selective removal of catechol in  
5 aqueous solution. Vinyl-functionalized 2,5-diallyloxyterephthalaldehyde (Da-V) was prepared as  
6 a building ligand. Da-V was then condensed with 1,3,5-tris(4-aminophenyl)benzene (Tab) to  
7 give a vinyl-functionalized COF DhaTab-V. Subsequently, 4-mercaptophenylboronic acid  
8 (4-MPBA) was covalently linked on DhaTab-V via thiol-ene click reaction to give  
9 phenylboronic acid-functionalized COF DhaTab-PBA. The adsorption isotherms, energetics and  
10 kinetics, and reusability of DhaTab-PBA for the adsorption and removal of catechol from  
11 aqueous solution were investigated in detail. This phenylboronic acid-functionalized COF is  
12 promising as sorbent for selective removal of catechol from aqueous medium with large  
13 adsorption capacity and good reusability.

## 1. INTRODUCTION

The wide use of catechol as chemical intermediates in industry causes potential environmental risks due to its high toxicity, carcinogenicity, high oxygen demand and low biodegradability.<sup>1-3</sup> Therefore, the removal of catechol from the polluted aqueous environment is of great importance for environmental remediation.<sup>4,5</sup> Up to date, quite a few techniques, such as adsorption,<sup>6,7</sup> electrochemical treatment<sup>8</sup> and chemical decomposition,<sup>9</sup> have been developed for removing catechol from aqueous environment. Adsorption is a frequently used manner in virtue of its features of high efficiency and easy operation.<sup>5</sup> Many sorbents such as activated carbon,<sup>10</sup> resin,<sup>7</sup> and montmorillonite,<sup>11</sup> have been used to remove catechol. However, there are still several limitations with these sorbents such as poor selectivity and low reusability.<sup>12,13</sup> Hence, the development of efficient and reusable sorbent is of great significance for the removal of catechol.

14-17

Covalent organic framework (COF), a rising type of crystalline porous polymers, has many desirable features, such as low mass density, regular pore structure, high surface area, facilely tailored functionality, and the like.<sup>18</sup> For these reasons, COF has received great attention in diverse fields, such as separation,<sup>19-23</sup> catalysis,<sup>24-26</sup> gas storage<sup>27-29</sup> and optoelectronics.<sup>30-32</sup> Despite COF has been applied for the adsorption of chemical pollutants, previous COF-based adsorption processes are mainly on the basis of hydrophobic interaction and  $\pi$ - $\pi$  stacking, and usually lack specificity.<sup>33,34</sup>

Introducing appropriate recognition moieties to COF is essential for improving adsorption specificity.<sup>35-38</sup> Boronic acid moiety enables covalent binding of cis-diols molecules to form five/six-membered cyclic esters.<sup>39-41</sup> Therefore, the introduction of boronic acid moiety to COF to develop functionalized sorbent is of great significance to enhance the ability for specific

1  
2  
3 recognition of cis-diols molecules.<sup>42</sup> Thiol-ene click strategy has been verified to be a feasible  
4 way to synthesize functionalized COF for diverse applications due to its high efficiency and  
5 selectivity.<sup>37,41</sup> For examples, thiol grafted imine-based and amino-modified COF have been  
6 synthesized via the thiol-ene click strategy for selective adsorption of heavy metal ions and  
7 carboxylic acid pesticides.<sup>37,41</sup>

8  
9  
10 Herein, we report a thiol-ene click approach for the fabrication of a novel phenylboronic  
11 acid-functionalized COF for selective removal of catechol from aqueous solution.  
12 Vinyl-containing ligand 2,5-diallyloxyterephthalaldehyde (Da-V) and  
13 1,3,5-tris(4-aminophenyl)benzene (Tab) are used as building ligands to prepare a  
14 vinyl-containing COF DhaTab-V. Subsequent thiol-ene click reaction of the prepared DhaTab-V  
15 with 4-mercaptophenylboronic acid (4-MPBA) gives phenylboronic acid-functionalized COF  
16 DhaTab-PBA with high adsorption capacity, and good adsorption selectivity and reusability for  
17 the removal of catechol from aqueous medium.

34  
35  
36 **2.1. Chemicals and Materials.** All of above-mentioned reagents and materials were at least  
37 analytical grade. 1,3,5-Tris(4-aminophenyl)benzene (Tab), 2,5-dihydroxyterephthalaldehyde (Da)  
38 were supplied by Bide Pharmatech Ltd. (Shanghai, China). Acetonitrile, ethanol,  
39 *N,N*-dimethylformamide (DMF), tetrahydrofuran (THF), methanol and acetone were provided  
40 by Sinopharm Chemical Reagent Co. Ltd. (Shanghai, China). Allyl bromide, *o*-dichlorobenzene  
41 (*o*-DCB), *n*-butyl alcohol (*n*-BuOH) and 4-mercaptophenylboronic acid (4-MPBA) were given  
42 by Macklin Biochemical Co. Ltd. (Shanghai, China). Catechol, resorcinol, hydroquinone, phenol  
43 and azodiisobutyronitrile (AIBN) were provided by Aladdin Chemistry Co. Ltd. (Shanghai,  
44 China).

1  
2  
3 **2.2. Instrumentation.** Powder X-ray diffraction (PXRD) patterns, thermogravimetric  
4 curves, Fourier transform infrared (FT-IR) spectra, nitrogen adsorption-desorption isotherms and  
5 Zeta potential data were acquired using the apparatuses described in ref. 43. <sup>1</sup>H nuclear magnetic  
6 resonance (NMR) analysis was done on a NMR spectrometer at 400 MHz ADVANCE III HD  
7 (Bruker, Switzerland). X-ray photoelectron spectra (XPS) were recorded on an Axis supra  
8 spectrometer with monochromatized Al<sub>Kα</sub> radiation ( $h\nu = 1486.6$  eV, 225 W) as X-ray source  
9 (Kratos, MA, UK). Transmission electron microscopy (TEM) and scanning electron microscope  
10 (SEM) images were obtained using the apparatuses described in ref. 27. UV-vis absorption  
11 analysis was done on a UV-3600PLUS220/230VC spectrophotometer (Shimadzu, Japan).

31

32 **2.3. Synthesis of ligand Da-V.** Da (0.26 g, 1.56 mmol) and potassium carbonate (1.80 g,  
33 13.02 mmol) were dispersed in 15 mL DMF. Then, allyl bromide (0.74 mL, 8.56 mmol) was  
34 dropwise added into the mixture with stirring. The mixture was heated to 70 °C, stirred for 12 h,  
35 and cooled down to room temperature. To the mixture, an appropriate volume of water was  
36 added to dissolve potassium carbonate. The resulting product was extracted with ethyl acetate (3  
37 × 10 mL). The collected organic extract was dried with anhydrous magnesium sulfate to remove  
38 residual water and condensed on a rotary evaporator. The obtained crude product was purified  
39 via recrystallization with a small volume of acetonitrile. The final product Da-V was  
40 yellow-green (0.33 g, 86.2%). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>, 298 K, TMS, ppm): δ 0.5 (s, 1H,  
41 CHO), 7.45 (s, 2H, ArH), 6.11-6.02 (m, 2H, CH), 5.45 (ddd,  $J = 17.2, 2.9, 1.5$  Hz, 2H, CH<sub>2</sub>),  
42 5.34 (ddd,  $J = 10.5, 2.6, 1.3$  Hz, 2H, CH<sub>2</sub>), 4.67 (dt,  $J = 5.2, 1.5$  Hz, 4H, OCH<sub>2</sub>).

1  
2  
3 **2.4. Synthesis of DhaTab-V.** Tab (56.20 mg, 0.16 mmol) and Da-V (59.04 mg, 0.24 mmol)  
4 were dispersed into a binary solvent of *o*-DCB (3 mL) and *n*-BuOH (3 mL) in a Schlenk tube (35  
5 mL, o.d. = 26, length = 125 mm) under 5-min ultrasonication. Then, acetic acid (6 M, 0.60 mL)  
6 mL, o.d. = 26, length = 125 mm) under 5-min ultrasonication. Then, acetic acid (6 M, 0.60 mL)  
7 was added to the mixture. The mixture was sonicated for 3 min, frozen under liquid nitrogen bath,  
8 and degassed with pump. After the tube was sealed with a screw cap, the mixture was heated at  
9 120 °C for 3 days. The resulting precipitate was collected via centrifugation and washed with  
10 DMF and THF for three times. The product was purified with fresh THF and dried at 50 °C for  
11 24 h under vacuum to afford DhaTab-V (90.30 mg, 84.7%).

34 **2.6. Adsorption experiments.** All of catechol standard solutions used in adsorption  
35 experiments except in pH effect study were prepared in phosphate buffer solution (PBS, 10  
36 mmol L<sup>-1</sup>, pH 8) for optimal adsorption of catechol. To study adsorption kinetics, 0.5 mg  
37 DhaTab-PBA and 2 mL standard catechol solution at certain initial concentration were added in a  
38 centrifugal tube (5 mL). After mechanical shaking (120 rpm) for a certain time in the range of  
39 0-300 min at room temperature, the mixture was centrifuged to collect the supernatant for UV-vis  
40 spectrophotometric determination of residual catechol in solution.

4  
5 solution.  
6  
7

8 To test the effect of pH, the pH of the aqueous standard catechol solution was adjusted to  
9  
10 3-10 with 1 mol L<sup>-1</sup> HCl and NaOH solution. To examine the effect of ionic strength, the  
11  
12 concentration of NaCl in the catechol standard solution was changed.  
13  
14

### 15 16 **3. RESULTS AND DISCUSSION**

17  
18 **3.1. Synthesis and characterization of DhaTab-PBA.** Figure 1 illustrates the design and  
19  
20 synthesis of DhaTab-PBA. In view of the large pore width (3.7 nm) of COF DhaTab prepared  
21  
22 from Da and Tab,<sup>21</sup> we chose DhaTab as the framework for further functionalization. We started  
23  
24 with the synthesis of the vinyl functionalized ligand Da-V from Da and allyl bromide via  
25  
26 nucleophilic substitution reaction. The vinyl-functionalized COF (DhaTab-V) was then prepared  
27  
28 via the condensation of Da-V and Tab with a solvothermal method. Finally, 4-MPBA was  
29  
30 introduced to fabricate the phenylboronic acid-functionalized COF (DhaTab-PBA) via thiol-ene  
31  
32 click reaction.

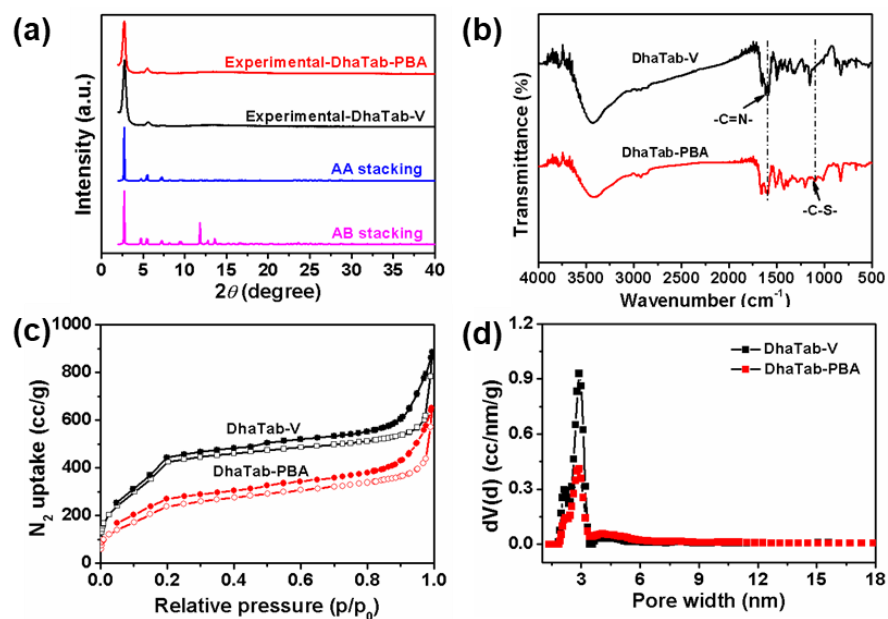

**Figure 1.** Illustration for the preparation of DhaTab-V via the condensation of Tab and Da-V and DhaTab-PBA via thiol-ene click reaction.

The incorporation of functional moiety on the pore surface via post-synthetic strategy inevitably affects the properties of COF, such as crystallinity, porosity and surface area.<sup>44</sup> Therefore, in the post-synthetic approach, a crucial balance between porosity and functionalization should be established to realize optimal experimental effects. Herein, we investigated different feed amounts of 4-MPBA on the adsorption of catechol on the phenylboronic acid-functionalized COF. The results show that DhaTab-PBA prepared from 0.26 mmol 4-MPBA and 20 mg DhaTab-V gives optimal adsorption capacity for catechol (Table S1).

PXRD experiment and Pawley refinement were carried out to reveal the crystal structures of DhaTab-V and DhaTab-PBA. The two peaks at  $2.8^\circ$  and  $5.6^\circ$  for DhaTab-V and its structure are in good agreement with an eclipsed AA model with the unit cell parameters of  $a = 36.2658 \text{ \AA}$ ,  $b = 38.1059 \text{ \AA}$ ,  $c = 3.8930 \text{ \AA}$ ,  $\alpha = \beta = 90^\circ$  and  $\gamma = 120^\circ$  (Figure 2a and Table S2). There is no great

1  
2  
3 difference between the experimental PXRD pattern and the refined eclipsed AA model PXRD  
4 pattern with factors of  $R_{wp} = 6.76\%$ ,  $R_{wp} (w/o\ bck) = 14.68\%$  and  $R_p = 5.01\%$  (Figure S1). The  
5  
6  
7 incorporation of phenylboronic acid to COF resulted in a minor loss of crystallinity compared  
8  
9  
10 with DhaTab-V (Figure 2a).

**Figure 2.** (a) PXRD patterns: experimental pattern of DhaTab-PBA (red line), experimental pattern of DhaTab-V (black line), simulated pattern of DhaTab-V for AA eclipsed model (blue line) and simulated pattern of DhaTab-V for AB eclipsed model (magenta line). (b) FT-IR spectra of DhaTab-V and DhaTab-PBA. (c) Nitrogen adsorption–desorption isotherms of DhaTab-V and DhaTab-PBA. (d) Pore size distribution of DhaTab-V and DhaTab-PBA.

The typical -OH stretching band ( $3280\text{ cm}^{-1}$ ) of Da disappeared but the C=O stretching peak ( $1670\text{ cm}^{-1}$ ) remained in the FT-IR spectra of Da-V (Figure S2a). The C=C stretching band of Da-V was not observed due to an overlap between C=C stretching ( $1695\text{--}1630\text{ cm}^{-1}$ ) and C=O stretching ( $1755\text{--}1665\text{ cm}^{-1}$ ) bands. However, new bands for C-O stretching ( $1210\text{ cm}^{-1}$ ) and C-H stretching ( $1380\text{ cm}^{-1}$  and  $1423\text{ cm}^{-1}$  from vinyl) appeared in the FT-IR spectra of Da-V (Figure

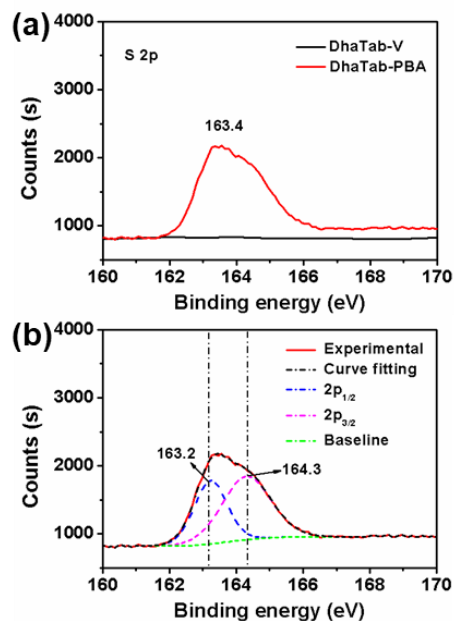

1  
2  
3 S2a). Meanwhile, the proton of C=C was verified by  $^1\text{H}$  NMR analysis (Figure S3). The above  
4 results show the successful vinyl modification of Da.  
5  
6

7  
8 The FT-IR spectra of DhaTab-V show the appearance of new band for C=N stretching  
9 (1605  $\text{cm}^{-1}$ ), the lack of N-H stretching band (3350-3450  $\text{cm}^{-1}$ ) of Tab, and the significant  
10 attenuation of the C=O stretching band (1670  $\text{cm}^{-1}$ ) of Da-V (Figure S2b), indicating the  
11 covalent framework formation of DhaTab-V. The weak C-S stretching band (1092  $\text{cm}^{-1}$ ) in the  
12 FT-IR spectra of DhaTab-PBA was due to the modification of 4-MPBA (Figure 2b).  
13  
14  
15  
16  
17  
18

19 The sulfur signal at 163.4 eV in the XPS spectra of DhaTab-PBA can be attributed to  
20 organosulfur compounds (Figure 3a).<sup>45,46</sup> The appearance of sulfur element in DhaTab-PBA  
21 composition also results from the modification of 4-MPBA (Table S3). With the theoretical  
22 calculation, XPS and elemental analysis (Figures 3 and S4), the percentages of 4-MPBA  
23 modified on COF were determined to be 18.8% to 21.9% of theoretical amount.  
24  
25  
26  
27  
28  
29

30 The introduction of phenylboronic acid moiety on COF resulted in no obvious change in the  
31 morphology of DhaTab-V (Figure S5), but significant decrease in the Brunauer-Emmett-Teller  
32 (BET) surface areas from 1032.5  $\text{m}^2 \text{g}^{-1}$  (DhaTab-V) to 621.5  $\text{m}^2 \text{g}^{-1}$  (DhaTab-PBA) (Figure 2c).  
33 Meanwhile, phenylboronic acid modification also made the total pore volume decrease from 0.88  
34  $\text{cm}^3 \text{g}^{-1}$  (DhaTab-V) to 0.62  $\text{cm}^3 \text{g}^{-1}$  (DhaTab-PBA) (Figure 2d).  
35  
36  
37  
38  
39  
40  
41

42 The fabricated DhaTab-V and DhaTab-PBA are comparatively stable up to 300  $^\circ\text{C}$  (Figure  
43 S6). Meanwhile, DhaTab-PBA is also stable in water/PBS (10 mM, pH 8) (Figure S7).  
44 Compared with DhaTab-V, DhaTab-PBA carries more negative charge due to the incorporation  
45 of boronic acid moiety (Figure S8).

**3.2. Adsorption kinetics for catechol.** To evaluate the kinetics for the adsorption of catechol on DhaTab-PBA, the time-dependent adsorption capacity ( $Q_t$ ) was obtained at an initial catechol solution of 0.025, 0.050 and 0.075 mg mL<sup>-1</sup> at room temperature (Figure 4a). The adsorption equilibrium for catechol on DhaTab-PBA was reached within 40 min, indicating the fast catechol adsorption. Further analysis of the time-dependent adsorption capacity reveals that the adsorption was better fitted to the pseudo-second-order kinetics than the first-order kinetics (Figure 4b and Figure S9; Table S4).

**Figure 4.** (a) Time-dependent adsorption for catechol on DhaTab-PBA at room temperature. (b) Plots of the pseudo-second-order kinetics for the catechol adsorption. (■) 0.025, (□) 0.050, and (▲) 0.075 mg mL<sup>-1</sup>.

**3.3. Effects of pH and ionic strength on the adsorption of catechol.** An appropriate pH is crucial to the recognition interaction between phenylboronic acid and cis-diols, depending on the dissociation constant (pKa) of phenylboronic acid molecule and cis-diol molecule.<sup>47</sup> Therefore, the effect of pH on the catechol adsorption was tested in a pH range of 3-10. The adsorption capacity for catechol on DhaTab-PBA obviously increased with pH in the range of 3-7, and remained almost constant from pH 7 to pH 10 (Figure S10a). The increasing dissociated 4-MPBA (pKa = 6.2, 298 K) over pH 6 is favorable for the formation of stable five/six-membered cyclic esters. Meanwhile, the un-dissociated catechol (pKa = 9.5, 298 K) at pH < 10 is favorable for the recognition of phenylboronic acid moiety. The variation of NaCl concentration in a range of 0-0.3 mol L<sup>-1</sup> gave no significant effect on the adsorption capacity for catechol on DhaTab-PBA (Figure S11). Therefore, further study was performed at pH 8 in the absence of salt.

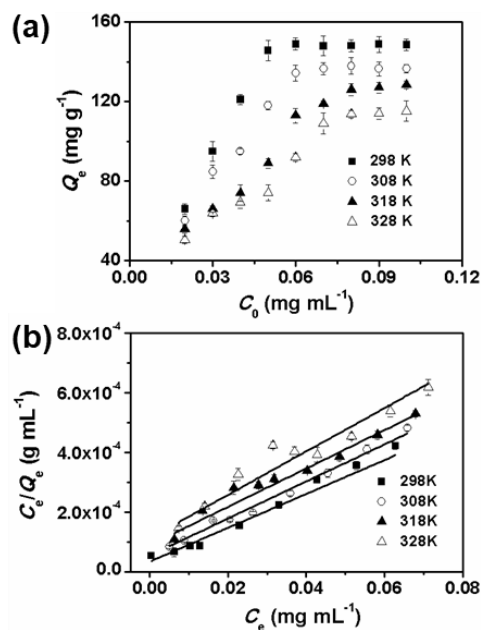

1  
2  
3 **3.4. Adsorption isotherms for catechol.** Adsorption experiments were carried out in an  
4 initial concentration range of 0.02-0.10 mg mL<sup>-1</sup> catechol solution at different temperature for 60  
5 min to evaluate the adsorption isotherms for catechol on DhaTab-PBA (Figure 5a). The  
6 adsorption capacity for catechol increased in the range of 0.02-0.05 mg mL<sup>-1</sup> and then levelled  
7 off with further increase of the initial catechol concentration. The adsorption isotherms could be  
8 well described with the Langmuir equation (Figure 5b):  
9  
10  
11  
12  
13  
14  
15

$$\frac{C_e}{Q_e} = \frac{1}{bQ_{\max}} + \frac{C_e}{Q_{\max}} \quad (1)$$

16  
17  
18  
19

20 where  $C_e$  (mg mL<sup>-1</sup>),  $Q_e$  (mg g<sup>-1</sup>) and  $Q_{\max}$  (mg g<sup>-1</sup>) are the concentration of catechol in solution  
21 at equilibrium, the experimental adsorption capacity at equilibrium and the theoretical maximal  
22 adsorption capacity, respectively,  $b$  (mL mg<sup>-1</sup>) represents the Langmuir constant.  
23  
24  
25  
26

27 The Langmuir constant ( $b$ ) and the maximum adsorption capacity ( $Q_{\max}$ ) were determined  
28 by plotting  $C_e/Q_e$  against  $C_e$  (Figure S14). The  $Q_{\max}$  for catechol on DhaTab-PBA was 160.0 mg  
29 g<sup>-1</sup>, obviously higher than that of DhaTab-V (89.3 mg g<sup>-1</sup>) at room temperature (Figure S12;  
30 Table S5). The result shows that the introduction of phenylboronic acid moiety into the COF  
31 significantly enhanced the adsorption of catechol.

**Figure 5.** (a) Adsorption isotherms for catechol adsorption on DhaTab-PBA in the range of 298-328 K. (b) The corresponding Langmuir plots in the range of 298-328 K.

To further study the adsorption behaviour of DhaTab-PBA, the adsorption isotherms were investigated in the temperature range of 298-328 K (Figure 5; Table S6). Free energy change ( $\Delta G$ , kJ mol<sup>-1</sup>), entropy change ( $\Delta S$ , J mol<sup>-1</sup> K<sup>-1</sup>), enthalpy change ( $\Delta H$ , kJ mol<sup>-1</sup>), and the thermodynamic equilibrium constant ( $K_0$ ) were calculated on the basis of eqs 2-4:

$$K_0 = \frac{Q_e}{C_e} \quad (2)$$

$$\Delta G = -RT \ln K_0 \quad (3)$$

$$\ln K_0 = \frac{\Delta S}{R} - \frac{\Delta H}{RT} \quad (4)$$

where  $R$  is the universal gas constant (8.314 J mol<sup>-1</sup> K<sup>-1</sup>).  $\ln K_0$  was obtained from the intercept by plotting  $\ln (Q_e/C_e)$  versus  $Q_e$ , while  $\Delta H$  and  $\Delta S$  were obtained from the plot of  $\ln K_0$  versus  $1/T$  (Figure S13).

1  
2  
3 Table S7 shows the determined  $\Delta G$ ,  $\Delta H$  and  $\Delta S$  for the adsorption of catechol on  
4 DhaTab-PBA. The results suggest that the adsorption of catechol on DhaTab-PBA is  
5 thermodynamically spontaneous (negative  $\Delta G$ ) with exothermic (negative  $\Delta H$ ) and  
6 random-decreased (negative  $\Delta S$ ) process. Therefore, the efficient catechol adsorption on  
7 DhaTab-PBA was controlled by the negative enthalpy change.  
8  
9  
10  
11  
12  
13  
14

15 **3.5. Adsorption selectivity.** Other types of compounds (resorcinol, hydroquinone, phenol,  
16 toluene, chlorobenzene and aniline) with similar chemical structures to cis-diols catechol were  
17 chosen as competitors to evaluate the selectivity of DhaTab-PBA (Figures S14 and S15).  
18 DhaTab-PBA was much more selective for the adsorption of catechol ( $Q_e = 152.6 \text{ mg g}^{-1}$ ) than  
19 other competitors ( $Q_e = 73.7\text{-}84.5 \text{ mg g}^{-1}$ ) (Figure S15). However, DhaTab-V showed similar  
20 adsorption capacity for catechol and competitors in the range of  $79.0\text{-}84.4 \text{ mg g}^{-1}$  (Figure S15).  
21 The results indicate that the recognition of phenylboronic acid moiety in addition to  $\pi\text{-}\pi$   
22 interaction resulted in the higher adsorption capacity for catechol on DhaTab-PBA.  
23  
24  
25

27  
28  
29  
30  
31  
32  
33  
34

35 **3.6. Desorption of catechol from DhaTab-PBA.** In view of green chemistry and practical  
36 application, an appropriate desorption condition is vital to the regeneration of the sorbent. Hence,  
37 the effect of the type of eluent, pH and elution time on the desorption of catechol from  
38 DhaTab-PBA were tested in views of the recognition of phenylboronic acid and  $\pi\text{-}\pi$  interaction.  
39 The results show that the adsorbed catechol was effectively desorbed from DhaTab-PBA with  
40 PBS (pH 3, 1 mL,  $10 \text{ mmol L}^{-1}$ ) in combination with ethanol (1 mL) for 3 min (Figure S16).  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 **3.7. Reusability.** The adsorption capacity for catechol on the regenerated DhaTab-PBA was  
51 examined to reveal the reusability of DhaTab-PBA. No obvious loss in the adsorption capacity  
52 for catechol was observed within five cycles of adsorption-desorption ( $Q_e = 145.4 \text{ mg g}^{-1} \pm 2.4$ ,  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 n=5) (Figure S17), indicating good reusability of DhaTab-PBA for catechol removal from  
4 aqueous solution. Five adsorption-desorption cycles led to a slight decrease in the crystallinity  
5 and surface area of DhaTab-PBA, but no obvious change in the pore volume and the zeta  
6 potential display, indicating the good stability of DhaTab-PBA (Figure S18).  
7  
8  
9  
10  
11  
12

13 **3.8. Comparison with other sorbents.** In comparison with DhaTab-V, DhaTab-PBA  
14 shows a significant improvement in adsorption capacity and selectivity for catechol (Figure 6a,  
15 Figure S12 and S19, Table S5), indicating the necessity and effectiveness for the introduction of  
16 phenylboronic acid to COF. Though the introduction of phenylboronic acid moiety on COF  
17 caused the reduction of surface areas and total pore volume, DhaTab-PBA still had higher  
18 adsorption capacity for catechol than DhaTab-V due to the high affinity of DhaTab-PBA to  
19 catechol from the selective recognition of the phenylboronic acid for catechol. In comparison  
20 with the other previous sorbents for catechol, DhaTab-PBA gave 1.1-4.6 times larger adsorption  
21 capacity (Table S8). Moreover, DhaTab-PBA showed faster adsorption kinetics than previous  
22 adsorbents except hydroxyl-containing gemini surfactants modified montmorillonite (Table S8).  
23

33  
34  
35  
36

37 **3.9. Adsorption capacity for catechol in environmental water.** To evaluate the feasibility  
38 of DhaTab-PBA in practical application, we used it as the sorbent to remove catechol from tap  
39 water, lake and river water samples. The experimental maximum adsorption capacity ( $Q'_{\max}$ ) for  
40 catechol on DhaTab-PBA in real water samples ranged from 133.3 mg g<sup>-1</sup> to 151.5 mg g<sup>-1</sup>,  
41 comparable with  $Q_{\max}$  (160.0 mg g<sup>-1</sup>) in the standard catechol solution (Table S9). The results  
42 reveal that DhaTab-PBA is a feasible and potential sorbent for catechol removal from  
43 environmental water.

#### 54 **4. CONCLUSIONS**

55  
56  
57  
58  
59  
60

1  
2  
3 In summary, we have reported a thiol-ene click strategy for the preparation of  
4 phenylboronic acid-functionalized COF (DhaTab-PBA) for catechol removal from aqueous  
5 solution. The recognition of phenylboronic acid,  $\pi$ - $\pi$  interaction and porous COF structure make  
6 DhaTab-PBA promising for the removal of catechol from environmental water with large  
7 adsorption capacity, and good adsorption selectivity and reusability.
